problem 1 - binary knapsack

- there are many items, each with a value and weight
- the knapsack you are wearing can only carry so much weight
- you want the most bang for your buck
 - what's the best *combination* of items to keep?
- combinatorial problem, np hard
 - approximate using a genetic algorithm
- this is like optimizing your inventory in games like skyrim
 - do you want 400 spoons in your pocket, each worth a dime, or do you want that gold bar that weighs a ton?
- formally, you want to maximize $z = \sum_{j=1}^n p_j x_j$ such that $\sum_{j=1}^n w_j x_j \leq c$ where $x_j \in \{0, 1\}$
 - for item j : p_j is the profit; w_j the weight; x_j whether to keep it

problem 2 - feature selection

- similar to the binary knapsack problem
- this time you have many data points
 - each data point consists of *features*
- each data point has an associated *output*
- you wish to eliminate the features that are least influential in producing a given output
 - this is like choosing what items to keep in your knapsack
- this is like weather forecasting
 - hundreds of features in data
 - which are most relevant?
 - which are noise?

- generate a population of randomized chromosomes
- calculate their fitness values
- perform a *tournament selection* to choose parent chromosomes
 - more fit individuals are more likely to be selected
 - introduces less diversity
- combine two parents to form two children via *single point crossover*
- mutate children randomly
- merge children into population, evicting the least fit individuals
 - this is the *elitism survivor selection*
- repeat

specific implementation

- fitness function
 - used the sum mentioned earlier
 - used linear regression and rmse for feature selection
